Abstract

In this paper, incremental exponential asymptotic stability of a class of switched Carathéodory nonlinear systems is studied based on the novel concept of measure of switched matrices via multiple norms and the transaction coefficients between these norms. This model is rather general and includes the case of staircase switching signals as a special case. Sufficient conditions are derived for incremental stability allowing for the system to be incrementally exponentially asymptotically stable even if some of its modes are unstable in some time periods. Numerical examples on switched linear systems switching periodically and on the synchronization of switched networks of nonlinear systems are used to illustrate the theoretical results.

Key words: Contraction; Incremental stability; Switched Carathéodory system; Synchronization.

1 Introduction

Studying incremental stability of nonlinear systems is particularly important in many application areas, including observer design and, more recently, consensus and synchronisation problems in network control where convergence analysis is a fundamental step (Wang & Slotine, 2005; Russo & di Bernardo, 2009a,b; Russo et al., 2010, 2011, 2013).

Since the early work by Lewis (1949); Demidovich (1967), contraction theory has been highlighted as a promising approach to study incremental exponential asymptotic stability (δEAS) of nonlinear systems (Lohmiller & Slotine, 1998; Forni & Sepulchre, 2014; Angeli, 2002); also see Jouffroy (2005) for an historical overview. In particular, as shown by Lohmiller & Slotine (1998), sufficient conditions for δEAS of a given nonlinear system over an invariant set of interest can be obtained by studying the matrix measure of its Jacobian induced by some vector norm. It is possible to prove, as done by Lohmiller & Slotine (1998); Russo et al. (2010), that if such measure is negative definite in that set for all time then any two trajectories will exponentially converge towards each other; the rate of convergence being estimated by the negative upper bound on the Jacobian measure.

Numerous applications of contraction analysis have been presented in the literature from observer design to the synthesis of network control systems. See e.g. Lohmiller & Slotine (1998); Forni & Sepulchre (2014); Russo et al. (2011). Remarkably, the problem of studying incremental stability of switched and hybrid systems has attracted relatively little attention despite the large number of potential applications, e.g. power electronic networks, variable structure systems, walking and hopping robots, to name just a few (di Bernardo et al., 2008; Liberzon, 2003; Cortes, 2008).

It has been suggested by Russo & di Bernardo (2011); di Bernardo et al. (2014) that extending contraction analysis to this class of systems can be a viable and effective approach to obtain conditions for their incremental asymptotic stability. Related approaches include the work on convergence of piecewise affine continuous systems presented by Pavlov et al. (2005b,a, 2007); Pavlov & van de Wouw (2008) and the recent conference papers (di Bernardo & Liuza, 2013; di Bernardo & Fiore, 2014).
One limitation of the existing extensions of contraction theory to switched systems, (e.g. di Bernardo et al., 2014), is that they rely on the use of a unique matrix measure to assess the Jacobian of each system modes. This is a particularly restricting assumption as it would be desirable to use measures induced by different norms to evaluate the Jacobian of each of the system modes. This would correspond to studying incremental stability of the switched system with multiple incremental Lyapunov functions rather than using a common one (which is much harder to find).

The aim of this paper is to address this problem and present conditions for contraction and incremental stability of a large class of switched Carathéodory systems. The key idea is to define a novel concept of matrix measure via multiple norms and exploit the transaction coefficients between these norms. In so doing, sufficient conditions are derived for incremental stability that allow for a system to be δEAS even if some of its modes are unstable (or not contracting) over some time intervals. The theoretical results are illustrated via their applications to some representative examples, including synchronisation in blinking networks.

2 Preliminaries

We focus on switched dynamical systems of the form

\[ \dot{x} = f(x, r(t)) \]  

(1)

where \( x \in \mathbb{R}^n \) and the switching signal \( r(t) \) is assumed to be a real-valued piecewise continuous (PWC for short) function with respect to time: there exist countable discontinuous points \( t_0 < t_1 < \cdots < t_i < \cdots \) such that \( r(t_i) \) exist and \( r(t_i) = r(t_i^+) \) for all \( t_i \). A typical example is the staircase function \( r(t) = \xi_i \), for \( t_i \leq t < t_{i+1}, i = 0, 1, \cdots \), for the increasing time sequence \( \{t_i\}_{i \geq 0} \), which has been widely used as switching signal in control systems (Liberzon, 2003).

Here we make the following hypothesis:

\( \mathcal{H}_1: \) For some \( C \subset \mathbb{R}^n \), the vector field \( f(x, r(t)) : C \times \mathbb{R} \rightarrow \mathbb{R}^n \) is (i) continuous with respect to \( (x, r) \); (ii) continuously differentiable with respect to \( x \); and (iii) there exists a Lebesgue measurable function \( m(t) \) such that \( |f(x, r(t))| \leq m(t) \) for all \( x \in C \) and \( t \in \mathbb{R} \).

It can be seen that under hypothesis \( \mathcal{H}_1 \), and with \( r(t) \) defined as above, the vector field \( f(x, r(t)) \) defines a Carathéodory switched system (Filippov, 1988). It can be proved that, given an initial condition in \( C \), a solution of a Carathéodory system exists and is unique (Hale, 1954). We define \( \phi(t; t_0, x_0, r_i) \) as the solution of (1) with \( x(t_0) = x_0 \) and the switching signal \( r(t) \), where \( r_i \) denotes the trajectory of \( r(t) \) up to \( t \), i.e., \( r_i = \{r(s)\}_{t_0 \leq s \leq t} \).

In this paper, \( \| \cdot \|_\chi \) stands for a specific vector norm in Euclidean space and the matrix norm induced by it, which can be defined in different ways that are all equivalent. The transaction coefficients from the norm \( \| \cdot \|_a \) to \( \| \cdot \|_b \) is defined as \( \beta_{ab} = \sup_{|x|_a = 1} |x|_b \) (Bourbaki, 1978).

A continuous function \( \alpha : [0, a) \rightarrow [0, \infty) \) is said to belong to class \( \mathcal{K} \) if (I) it is strictly increasing; (II) \( \alpha(0) = 0 \). And, a continuous function \( \beta(p, t) : [0, a) \times [0, \infty) \rightarrow [0, \infty) \) is said to belong to class \( \mathcal{K}\mathcal{L} \) if (I) for each fixed \( t \), the function \( \beta(p, t) \) belongs to class \( \mathcal{K} \); (2) for each fixed \( p \), the function \( \beta(p, t) \) is decreasing with respect to \( t \) and \( \lim_{t \rightarrow \infty} \beta(p, t) = 0 \). In addition, if a function \( \beta(p, t) \) of class \( \mathcal{K}\mathcal{L} \) converges to 0 exponentially as \( t \rightarrow \infty \), \( \beta(p, t) \) is said to be of class \( \mathcal{E}\mathcal{K}\mathcal{L} \). Here, we give the following definition of incremental stability from Angeli (2002) with modifications.

**Definition 1** System (1) is said to be incrementally asymptotically stable (δEAS for short) with \( r(t) \) in the region \( C \subset \mathbb{R}^n \) if there exists a function \( \beta(s, t) \) of class \( \mathcal{K}\mathcal{L} \) such that for any initial data \( x_0, y_0 \in C \) and starting time \( t_0 \), the following property holds

\[ |\phi(t + t_0; t_0, x_0, r_t) - \phi(t + t_0; t_0, y_0, r_t)| \leq \beta(|x_0 - y_0|, t) \]

for some norm \( \| \cdot \| \). If \( \beta(s, t) \) is picked independently of the initial time \( t_0 \), then system (1) is said to be incrementally uniformly asymptotically stable (δUES for short). If \( \beta(s, t) \) is of class \( \mathcal{E}\mathcal{K}\mathcal{L} \), then system (1) is said to be incrementally exponentially asymptotically stable (δEUES for short) and incrementally uniformly exponentially asymptotically stable (δUEUES for short) if \( \beta(s, t) \) is chosen independently of \( t_0 \).

**Definition 2** A set \( C \subset \mathbb{R}^n \) is said to be a \( \kappa \)-reachable set if there exists a continuously differentiable curve \( \gamma(s) : [0, 1] \rightarrow C \) that links \( x_0 \) and \( y_0 \), i.e., \( \gamma(0) = x_0 \) and \( \gamma(1) = y_0 \), and satisfies \( |\gamma'(s)|_{\chi(t_n)} \leq \kappa|x_0 - y_0|_{\chi(t_n)} \) for all \( s \in [0, 1] \) and some constant \( \kappa > 0 \), independently of \( x_0 \) and \( y_0 \).

3 Switched matrix measures and general contraction analysis

The matrix measure induced by the vector norm \( \| \cdot \|_\chi \), where \( \chi \) is the index for the norm being used, is defined as

\[ \mu_\chi(A) = \lim_{h \rightarrow 0+} \frac{1}{h} [|((I_n + hA)|_\chi - 1] \]

for a square matrix \( A \in \mathbb{R}^{n,n} \) and was used for the contraction analysis of smooth nonlinear systems, see e.g. Lohmiller & Slotine (1998).

Given a PWC function \( \chi(t) \), the left (right) limit of \( |\cdot|_{\chi(t)} \) at time \( t \) is defined as \( \lim_{h \rightarrow 0+} |x|_{\chi(t+h)} \) (\( \lim_{h \rightarrow 0+} |x|_{\chi(t-h)} \)) if it exists for all \( x \in \mathbb{R}^n \), and is denoted by \( |\cdot|_{\chi(t)} \) respectively. We say that the switched norm \( |\cdot|_{\chi(t)} \) is continuous at time \( t \) if \( |x|_{\chi(t-\epsilon)} = |x|_{\chi(t+\epsilon)} = |x|_{\chi(t)} \) for all \( x \in \mathbb{R}^n \), i.e., if \( |\cdot|_{\chi(t)} \) is left and right continuous. We say that \( |\cdot|_{\chi(t)} \) is
uniformly equivalent if there exists a constant $D > 0$ such that $|x|^\chi(t) \leq D|x|^\chi(s)$ for all $x \in \mathbb{R}^n$ and $t, s \in \mathbb{R}$.

We can now extend the definition of matrix measure to the case of multiple norms, taking the time-varying nature of $\chi(t)$ into consideration, as follows.

**Definition 3** The switched matrix measure with respect to multiple norms $| \cdot |_{\chi(t)}$ is defined as

$$\nu_{\chi}(A) = \lim_{h \to 0} \frac{1}{h} \sup_{|\chi(t+h)|=1} \left[ [(I_n + hA)x|_{\chi(t+h)}] - 1 \right]$$

if the limit exists, where $\lim$ stands for the limit superior.

It can be seen that $\chi(t)$ is constant over an interval, say $[t, t+\delta)$, then $\nu_{\chi}(A) = \mu_{\chi}(A)$ over that interval.

The existence of the switched matrix measure is related to the partial differential of the switched norm $| \cdot |_{\chi(t)}$ as follows

$$\frac{\partial}{\partial t} (| \cdot |_{\chi(t)}) = \lim_{h \to 0} \sup_{|\chi(t+h)|=1} \frac{|x|_{\chi(t+h)} - 1}{h}.$$ 

We say that the multiple norm $| \cdot |_{\chi(t)}$ is right regular at time $t$ if $\partial_t (| \cdot |_{\chi(t)})$ exists. Thus, we have

**Proposition 1** If $| \cdot |_{\chi(t)}$ is right regular at $t$, then (i). $| \cdot |_{\chi(t)}$ is right continuous at $t$; (ii). $\nu_{\chi}(A)$ exists at $t$.

**Proof** The first statement is straightforward from the definitions of $\partial_t (| \cdot |_{\chi(t)})$ and right continuity of $| \cdot |_{\chi(t)}$.

The quotient term of the definition of $\nu_{\chi}(A)$ gives

$$\frac{1}{h} \sup_{|\chi(t+h)|=1} \left[ [(I_n + hA)x|_{\chi(t+h)}] - 1 \right] + [(I_n + hA)x|_{\chi(t)}] + \mu_{\chi}(A)h + o(h)]$$

where $o(h)$ is an infinitesimal term with $\lim_{h \to 0} o(h)/h = 0$. So, $\nu_{\chi}(A) \leq \mu_{\chi}(A) + \partial_t (| \cdot |_{\chi(t)})$ (statement (ii)).

Using the definition of switched matrix measure, we extend Coppel inequality (Coppel, 1965) as follows.

**Lemma 1** Suppose that $| \cdot |_{\chi(t)}$ is right-regular in $[t_1, t_2]$. Consider the following time-varying Carathéodory dynamical system $\dot{x}(t) = A(t)x(t)$ with some PWC matrix-valued function $A(t) \in \mathbb{R}^{n \times n}$ and $x(t) \in \mathbb{R}^n$. If $\nu_{\chi}(A(t)) \leq \alpha(t)$ for some measurable function $\alpha(t)$ for $t \in [t_1, t_2]$, then

$$|x(t_2)|_{\chi(t_2)} \leq \exp \left( \int_{t_1}^{t_2} \alpha(t)dt \right) |x(t_1)|_{\chi(t_1)}.$$

**Proof** For any $t \in (t_1, t_2)$ except discontinuous points of $A(t)$, consider the following quotient

$$I(h) = \frac{1}{h} \left[ |x(t + h)|_{\chi(t+h)} - |x(t)|_{\chi(t)} \right]$$

$$= \frac{1}{h} \left[ |x(t) + \int_{t}^{t+h} A(s)x(s)ds|_{\chi(t+h)} - |x(t)|_{\chi(t)} \right]$$

$$= \frac{1}{h} \left[ \left( |(I_n + hA(t))x(t)| + \int_{t}^{t+h} |A(s)x(s)| \right) - |A(t)x(t)| \right]$$

$$\leq \frac{1}{h} \left[ |(I_n + hA(t))x(t)|_{\chi(t+h)} - |x(t)|_{\chi(t)} + o(h) \right]$$

which implies that $\lim_{h \to 0} I(h) \leq \nu_{\chi}(A(t))|x(t)|_{\chi(t)}$. That is, $D^+ |x(t)|_{\chi(t)} \leq \nu_{\chi}(A(t))|x(t)|_{\chi(t)} \leq \alpha(t)|x(t)|_{\chi(t)}$ holds for almost every $t \in [t_1, t_2]$, where $D^+$ stands for the Dini derivative. Thus, Ineq. (3) holds, noting that $x(t)$ is continuous with respect to $t$.

We make the following hypothesis on the multiple norm.

$H_2$: $| \cdot |_{\chi(t)}$ is right-regular everywhere but at the time instants $\{\tilde{t}_j\}$, it is right-continuous and uniformly equivalent, and its left-limit exists at each $\tilde{t}_j$.

Thus, we denote by $\tilde{N}(t, s) = \# \{s < \tilde{t}_j < t\}$, the number of time instants $\tilde{t}_j$ in the time interval $(s, t)$; obviously, $\tilde{N}(t) = \tilde{N}(t, t_0)$. Here, # stands for the cardinality of a set. In addition, we make the following assumption.

$H_3$: There exists a $r$-reachable set (Russo et al., 2010) $C \subset \mathbb{R}^n$ which is a forward-invariant for (1).

Then, we have a general result on $\delta EAS$ of switched dynamical system (1) by contraction analysis in multiple norms.

**Theorem 1** Suppose that hypotheses $H_{1,2,3}$ hold and that $r(t)$ is PWC. If there exist a measurable function $\alpha(t)$, non-negative constants $\beta_j$, $j = 1, 2, \cdots, c > 0$, and $T_0 > 0$, such that, for all $x \in C$, the following conditions hold

$$\nu_{\chi}(A(t)) \left( \frac{\partial f}{\partial x}(x, r(t)) \right) \leq \alpha(t), \forall t \neq \tilde{t}_j, x \in C$$

$$| \cdot |_{\chi(\tilde{t}_j)} \leq \beta_j | \cdot |_{\chi(\tilde{t}_j)}, \forall j$$

(4) (5)
and, for all $T > T_0$,
\[
\frac{1}{T} \left[ \int_{t_0}^{T+t_0} \alpha(t) dt + \sum_{j=1}^{\bar{N}(t_0 + T)} \log(\beta_j) \right] < -c,
\]
then system (1) is $\delta EAS$ in $C$ with respect to $r(t)$; if (6) holds for some $\gamma > 0$ independent of $t_0$, then (1) is $\delta UEAS$ with respect to $r(t)$ in $C$. In addition, the exponential convergence rate can be estimated as $O(\exp(-c(t - t_0)))$.

**Proof** For any $x_0, y_0 \in C$, $C$ being $\kappa$-reachable for some $\kappa > 0$ implies, from Definition 2, that there exists a continuously differentiable curve $\gamma(s) : [0, 1] \to C$ such that $\gamma(0) = x_0$ and $\gamma(1) = y_0$, and $|\gamma'(s)|_{X(t_0)} \leq \kappa|x_0 - y_0|_{X(t_0)}$, for all $s \in [0, 1]$.

Let $\psi(t, s) = \phi(t; t_0, \gamma(s), r_t)$, $s \in [0, 1]$, be the solution of (1) with initial value $\psi(t_0, s) = \gamma(s)$. Since $f(x, r(t))$ is continuous with respect to $(x, t)$ except for the switching time points $\{t_j\}$ and continuously differentiable with respect to $x$, then $\phi(t; t_0, x_0, r_t)$ is continuously differentiable with respect to the initial value $x_0$. Let $x_0 = \gamma(s)$. Then, $w = \frac{\partial \psi}{\partial s}$ is well defined and continuous. By the same algebraic manipulations first presented by Russo et al. (2010), except for $\{t_j\}$, $w(t, s)$ is the Carathéodory solution of:
\[
\begin{align*}
\dot{w} &= \frac{\partial}{\partial s} \phi(t; r(t))w \\
|w(t_0, s)| &= \gamma'(s)
\end{align*}
\] (7)

Consider the sequence $|w(\tilde{t}_j, s)|_{X(\tilde{t}_j)}$ of Eq. (7). For all $s \in [0, 1]$, by the extended Coppel inequality (3) and condition (4), we have
\[
|w(\tilde{t}_j, s)|_{X(\tilde{t}_j)} \leq \exp \left[ \int_{t_{j-1}}^{\tilde{t}_j} \alpha(t) dt \right] |w(\tilde{t}_{j-1}, s)|_{X(\tilde{t}_{j-1})}.
\]

Using inequality (5) between $|\cdot|_{X(\tilde{t}_{j-1})}$ and $|\cdot|_{X(\tilde{t}_{j})}$, gives
\[
|w(\tilde{t}_j, s)|_{X(\tilde{t}_j)} \leq \beta_j |w(\tilde{t}_j, s)|_{X(\tilde{t}_j)}
\]
\[
\leq \beta_j \exp \left[ \int_{t_{j-1}}^{\tilde{t}_j} \alpha(t) dt \right] |w(\tilde{t}_{j-1}, s)|_{X(\tilde{t}_{j-1})}
\]

Then, iterating down to $i < j$, we have
\[
|w(\tilde{t}_j, s)|_{X(\tilde{t}_i)} \leq \prod_{k=i+1}^{j} \beta_k \exp \left[ \int_{t_i}^{\tilde{t}_i} \alpha(t) dt \right] |w(\tilde{t}_i, s)|_{X(\tilde{t}_i)}.
\]

For any $t$, noting that from definition $\tilde{t}_{\bar{N}(t)+1} \geq t > \bar{t}_{\bar{N}(t)}$,
we have
\[
|w(t, s)|_{X(t)} \leq \exp \left[ \int_{\tilde{t}_{\bar{N}(t)}}^{t} \alpha(\tau) d\tau \right] |w(\tilde{t}_{\bar{N}(t)}, s)|_{X(\tilde{t}_{\bar{N}(t)})}
\]
\[
\leq \exp \left[ \int_{\tilde{t}_{\bar{N}(t)}}^{T_0} \alpha(\tau) d\tau \right] \cdot \exp \left( \sum_{i=1}^{\bar{N}(t)} \log(\beta_i) \right)
\]
\[
+ \int_{t_0}^{\tilde{t}_{\bar{N}(t)}} \alpha(\tau) d\tau |w(\tilde{t}_0, s)|_{X(\tilde{t}_0)}
\]

Hence, we obtain
\[
|w(t, s)|_{X(t)} \leq \exp(-c(t - t_0))|\gamma'(s)|_{X(t_0)},
\]
for all $t > t_0 + T_0$. Since $c$ is independent of $s$, $\delta EAS$ can be derived by following similar arguments as presented by Russo et al. (2010). In detail, since $|\cdot|_{X(t)}$ is uniformly equivalent, there exists $D > 0$ such that $|x|_{X(t)} \leq D |x|_{X(t)}$ for any $x \in \mathbb{R}^n$ and $t, t' \geq t_0$. Then, by (8), we have
\[
|\phi(t; x(0), r_t) - \phi(t; y(0), r_t)|_{X(t)} \leq D |x - y|_{X(t)}
\]
\[
= D \int_0^1 \frac{\partial \psi}{\partial s} \left[ |\psi(t, s)|_{X(t)} \right] ds \leq D \int_0^1 |w(t, s)|_{X(t)} ds
\]
\[
\leq D \int_0^1 \exp(-c(t - t_0)) |\gamma'(s)|_{X(t_0)} ds
\]
\[
= D \kappa \exp(-c(t - t_0)) |x_0 - y_0|_{X(t_0)}
\]
which converges to zero exponentially. This proves that system (1) is $\delta EAS$.

If (6) holds for some $c > 0$ independently of $t_0$, then (8) holds independently of $t_0$ if $t - t_0 > T_0$, which implies $\lim_{t \to \infty} |w(t)|_{X(t)} = 0$ is uniform with respect to $t_0$. By the arguments above, system (1) is $\delta UEAS$. In addition, inequality (10) implies that the exponential convergence rate can be estimated as $O(\exp(-c(t - t_0)))$.

Note that $c$ is an estimate of the exponential convergence rate and also an index of the average contraction rate of (1).

As a simple example to illustrate this result, define a switched matrix measure based on the following multiple norms: $|x|_{P(t)} = \sqrt{x^T P(t) x}$. Here, $P(t) \in \mathbb{R}^{n \times n}$ is a differentiable matrix-value function where each $P(t)$ is a symmetric positive definite matrix such that its largest eigenvalue $\lambda_{\max}(P(t))$ the smallest eigenvalue $\lambda_{\min}(P(t))$ is upper bounded and lower-bounded positively respectively. Then, for any $A \in \mathbb{R}^{n \times n}$, by simple algebraic manipulations, it can be shown that the induced switched matrix measure is $\nu_{P(t)}(A) = \frac{1}{2} \lambda_{\max}[P^{-1/2}(t)(P(t)A + A^T P(t) + \dot{P}(t))P^{-1/2}(t)]$. 

Now, consider the linear time-varying (LTV) system $\dot{x} = A(t)x + I(t)$ with some PWC matrix function $A(t)$. Then, (6) in Theorem 1 can be fulfilled by assuming that it holds that $P(t)A(t) + A(t)^T P(t) + P(t) < 0$ for almost every $t$. A similar condition can also be obtained by using the theory of convergent systems (Pavlov et al., 2007).

**Remark 1** Analogous arguments to those presented by Lohmiller & Slotine (1998) and Russo et al. (2010) can be followed to prove that the contracting system converges towards a periodic solution if $r(t)$ is periodic. Indeed, in this case the time instants where $r(t)$ switches, say $\{t_i\}$, are also periodic with period $T$ and so is the function $N(t, s) = N(t + T, s + T)$ for all $t > s$. Then, inequality (6) can be fulfilled by assuming that

$$\frac{1}{T} \left[ \int_{t_0}^{t_0+T} \alpha(t)dt + \sum_{j=1}^{J} \log(\beta_j) \right] < -c.$$  \hfill (11)

where $J$ is the number of switches in one period. (Note that this inequality holds independently of the initial time $t_0$, due to the periodicity.) From Theorem 1, one can conclude that system (1) is $\delta EAS$. The existence of a periodic solution of (1) follows by using the contraction mapping.

4 Contraction analysis of staircase switching and trans- action coefficients between norms

As a special case and an important application, in this section, we assume that the switching signal $r(t)$ of the switched system (1) is a staircase function:

$$\mathcal{H}_4: r(t) = \xi_i, \quad t_i \leq t < t_{i+1}, \quad i = 0, 1, \ldots,$$

with an increasing time point sequence $\{t_i\}$ with $t_i = 0$ and $\lim_{i \to \infty} t_i = \infty$, where $\xi_i \in \Xi$ where $\Xi$ is a countable set.

Let $\Delta_i = t_{i+1} - t_i > 0$ be the interval between two points, and $N(t, s) = \#\{i : s < t_i < t\}$, be the number of time instants when $r(t)$ switches that fall in the time interval $[s, t]$, in particular, $N(t) = N(t, t_0)$.

By using multiple norms $\| \cdot \|_{\chi(t)}$ with $\chi(t) = r(t)$, we obtain the following result as a consequence of Theorem 1.

**Corollary 1** Suppose that hypotheses $\mathcal{H}_{1,2,3,4}$ hold. If there exists constants $\alpha_i$, nonnegative constants $\beta_i$, $i = 1, 2, \ldots$, $c > 0$ and $T_0 > 0$ such that, for all $i$ and $x \in \mathcal{C}$, the following conditions hold

$$\mu_{\xi_i} \left( \frac{\partial f}{\partial x}(x, \xi_i) \right) \leq \alpha_j, \quad | \cdot |_{\xi_{i+1}} \leq \beta_j | \cdot |_{\xi_i}, \quad \forall \ j$$  \hfill (12)

and, for all $T > T_0$,

$$\frac{1}{T} \left\{ N(t_0+T) \sum_{i=0}^{N(t_0+T)} \alpha_i \Delta_i + \log(\beta_i) \right\} + \alpha N(t_0+T)+1 \left[ t_0 + T - t_N(t_0+T) \right] < -c,$$  \hfill (13)

then (1) is $\delta EAS$ with respect to $r(t)$ in $\mathcal{C}$; if (13) holds for some $c > 0$ independently of $t_0$, then (1) is $\delta U EAS$ with respect to $r(t)$ in $\mathcal{C}$. Moreover, the exponential convergence rate is estimated as $O(\exp(-c(t - t_0)))$.

**Proof** Let $\alpha(t) = \alpha_i$ if $t \in [t_i, t_{i+1})$. We have

$$\nu_r(t) \left( \frac{\partial f}{\partial x}(x, \xi_i) \right) = \mu_r(t) \left( \frac{\partial f}{\partial x}(x, \xi_i) \right) \leq \alpha(t), \quad \forall \ t \neq t_i.$$  

Note that

$$\frac{1}{T} \int_{t_0}^{t_0+T} \alpha(t)dt = \frac{1}{T} \int_{t_0}^{t_0+T} \left[ \alpha N(t_0+T)+1 \left( t_0 + T - t_N(t_0+T) \right) + \alpha_0 \Delta_0 + \sum_{i=0}^{N(t_0+T)-1} \alpha_i \Delta_i \right].$$

Under condition (13), one can conclude that there exists $T_1 > 0$ such that

$$\frac{1}{T} \left[ \int_{t_0}^{t_0+T} \alpha(t)dt + \sum_{i=0}^{N(t_0+T)-1} \beta_i \right] < -c$$  \hfill (14)

for all $T > T_1$. By employing Theorem 1, $\delta EAS$ of (1) can be proved. Furthermore, if (13) holds independently of the initial time $t_0$, and therefore (14) holds independently of $t_0$, then (1) is $\delta U EAS$ with respect to $r(t)$ in $\mathcal{C}$. The exponential convergence rate can be derived as done in the proof of Theorem 1.

We can exploit Corollary 1 when considering the case where $r(t)$ ($\xi_i$) takes values in a finite set $\Omega = \{1, \ldots, K\}$. Specifically, define for any $t > s \geq 0$

$$\mathcal{T}_k(s, t) = \{ \tau \in [s, t] : r(\tau) = k \},$$

$$\mathcal{N}_k(s, t) = \# \{ i : r(t_i-1) = k, \text{ and } r(t_i) = k, \ s \leq t_i \leq t \},$$

and constants $\alpha_k$ and $\beta_{kl} > 0$, $k, l = 1, \ldots, K$ such that

$$\mu_k \left( \frac{\partial f}{\partial x}(x, k) \right) \leq \alpha_k, \ | \cdot |_{|x| \leq \beta_{kl}} \cdot |x|.$$  \hfill (15)

Then letting $\alpha(t) = \alpha_i$ when $t \in [t_i, t_{i+1})$, it can be seen that inequality (13) in Corollary 1 can be derived if the
following condition holds for all $T > T_0$:

$$
\frac{1}{T} \sum_{k=1}^{K} \left( \alpha_k T_k (t_0, t_0 + T) + \sum_{i=1}^{K} \log(\beta_{kl}) N_{kl} (t_0, t_0 + T) \right) \\
\leq -c.
$$

(16)

Alternatively, condition (16) can be replaced by the assumption that there exists some $T_1 > 0$ such that for each $T_1$-
length interval, $[nT_1, (n+1)T_1]$, it holds that

$$
\frac{1}{T_1} \sum_{k=1}^{K} \left( \alpha_k T_k (nT_1, (n+1)T_1) + \sum_{i=1}^{K} \log(\beta_{kl}) N_{kl} (nT_1, (n+1)T_1) \right) \\
\leq -c, \quad \forall \ n \geq 0.
$$

(17)

Remark 2 From Ineq. (17), in the case that all $\alpha_k < 0$, $k = 1, \cdots, K$, which implies that all subsystems are con-
tracting and hence incrementally stable, the switched system is incrementally stable if the duration of the mode in which each subsystem is active is sufficiently long.

More specifically, if all norms $\| \cdot \|_k$ are identical – and simply denoted by $\| \cdot \|$ – then $\beta_{kl} = 1$, and inequality (13) can be fulfilled by simply assuming that $(1/T) \sum_{k=1}^{K} \alpha_k T (t, t + T) \leq -c$ holds for all $t > 0$. Thus, one can see that if $\alpha_k < 0$ holds for all $k = 1, \cdots, K$ (with respect to the same norm), then (1) is incrementally stable, which coincides with the results by Russo & di Bernardo (2011).

The conditions of Theorem 1 and Corollary 1 as well as (16) depend on two quantities: the matrix measures $\alpha_k$ of the Jacobian of the dynamical system for each constant value of $r(t)$, and the transaction coefficients $\beta_{kl}$ between norms. As system (1) is defined in a finite dimensional Euclidean space, these vector norms are equivalent, i.e., there exist positive constants $\beta_{kl}$ such that $\| x \| \leq \beta_{kl} \| x \|_k$ holds for all $x \in \mathbb{R}^n$. The role of such transaction coefficients will be further investigated below.

For illustration, consider the LTV system

$$
\dot{x}(t) = A(r(t))x(t) + B
$$

(18)

where $r(t) : [0, \infty] \rightarrow C \equiv \{1, 2\}$ with $A = A(1)$ or $A(2)$ and $B \in \mathbb{R}^2$. We assume that the linear system is switched between two constant matrices periodically with identical frequency $\varphi_T$. Consider two vector norms $\| \cdot \|_{1,2}$, corresponding to matrix measures $\mu_{1,2}$ respectively, with transaction coefficients $\beta_{12}$ and $\beta_{21}$. Corollary 1, specifically condition (17), yields that the following inequality is a sufficient conditions for $\delta$UEAS of system (18):

$$
\frac{1}{2} \left[ \mu_1(A(1)) + \mu_2(A(2)) + \varphi_T (\log \beta_{12} + \log \beta_{21}) \right] \\
< -c.
$$

(19)

for some $c > 0$.

We now discuss the relationship between different classes of vector norms in greater detail.

**Quadratic norms.** The quadratic norm is defined as $\| x \|_Q = \sqrt{x^\top P x}$ for some positive definite matrix $P$. For another $\| x \|_Q = \sqrt{x^\top Q x}$ with symmetric positive definite matrix $Q$. Then, we have

$$
\| x \|_Q \leq \sqrt{\lambda_{\max}(P^{-1/2}QP^{-1/2}) \| x \|_P}
$$

(20)

for all $x \in \mathbb{R}^n$, where $\lambda_{\max}(A)$ denotes the largest eigenvalue of a symmetric square matrix $A$. The proof of this s-
tatement is straightforward and omitted here for the sake of brevity.

A a first example, we take $A(1) = \begin{pmatrix} 0 & -1 \\ 2 & -3 \end{pmatrix}$, $A(2) = \begin{pmatrix} 0 & -11 \\ 2 & -33 \end{pmatrix}$. It is easy to see that, using the matrix mea-
sures $\mu_i(\cdot)$ induced by the quadratic weighted vector norm $\| x \|_{\Theta_i} := \| \Theta_i x \|_2$, $i = 1, 2$ respectively, the matrix measures $\mu_i[A(i)]$ with

$$
\Theta_1 = \begin{pmatrix} 0.707 \ 0.447 \\ 0.707 \ 0.894 \end{pmatrix}^{-1}, \quad \Theta_2 = \begin{pmatrix} 0.998 \ 0.322 \\ 0.0618 \ 0.947 \end{pmatrix}^{-1}
$$

are negative for $i = 1$ and $i = 2$. In particular, $\mu_1[A(1)] \leq -1 := \alpha_1$ and $\mu_2[A(t, 2)] \leq -0.6807 := \alpha_2$.

From the results reported in Sec. 2, we get from Ineq. (20) that: $\| x \|_{\Theta_1} \leq 1.796 \| x \|_{\Theta_2}$ and $\| x \|_{\Theta_2} \leq 1.05 \| x \|_{\Theta_1}$; therefore condition (5) remains satisfied with $\beta_{12} := 1.796$ and $\beta_{21} := 1.05$. Assuming a switching frequency of $\varphi_T = 1$ Hz between the two modes, we have $\Delta_i = 1$ s for all $i$. Therefore (19) is satisfied and (18) is incrementally stable in $\mathbb{R}^2$.

The evolution of the norm of the error for two trajectories starting at initial conditions $[0.5, 0.1]$ and $[0.4, 0.1]$ respectively is shown in Fig. 1 when $B = [0 \ 0]$ and $B = [1 \ 1]$ re-
spectively. In both cases we observe incremental stability as expected. Note that the use of two different weighted norms makes proving incremental stability much simpler than if one common metric had to be used for both modes as re-
quired by previous results (e.g. Russo & di Bernardo, 2011; di Bernardo et al., 2014).

Next, we take $A(1) = \begin{pmatrix} -1.3481 \ -2.9306 \\ -2.4538 \ -1.2755 \end{pmatrix}$, $A(2) = \begin{pmatrix} -11.2237 \ 7.0628 \\ -1.7413 \ 1.5119 \end{pmatrix}$. It can be seen that $A(1)$ is Huwitz
The results presented by Porfiri et al. (2008) cannot be applied for this specific situation. Nevertheless our extension of contraction analysis to switched systems gives a simple and viable set of conditions that can be used to prove that indeed the system is incrementally stable.

More specifically, from the properties of matrix measures,
\[
\frac{1}{2} (\mu(A(1)) + \mu(A(2))) \geq \mu(A_m) \\
\geq \max (\mathbb{R}|(\lambda) : \lambda \in \sigma((A_m))) > 0
\]

it is not possible to find a uniform norm such that the average of the matrix measures of the switched matrices induced by this matrix norm is negative as required by condition (19). Therefore, in this case, multiple norms must be utilised for proving contraction and \(\delta\)EAS of the system.

**Weighted \(L_p\)-norms.** The weighted \(L_p\)-type norms with \(1 \leq p \leq \infty\) are defined as follows.

- Weighted \(L_p\)-norm: \(\|x\|_{\xi,p} = (\sum_{i=1}^{n} \xi_i |x_i|^p)^{1/p}\) for some \(p \geq 1\) and \(\xi = [\xi_1, \ldots, \xi_n]^T\) with \(\xi_i > 0\) for all \(i = 1, \ldots, n\);
- Weighted \(L_\infty\)-norm: \(\|x\|_{\xi,\infty} = \max_i \xi_i |x_i|\) for some \(\xi = [\xi_1, \ldots, \xi_n]^T\) with \(\xi_i > 0\) for all \(i = 1, \ldots, n\).

Their transaction coefficients are summarised by the following proposition.

**Proposition 2** For \(p > q \geq 1\) with \(p\) possibly equal to \(\infty\) and two component-wise vectors \(\xi = [\xi_1, \ldots, \xi_n]^T\) and \(\eta = [\eta_1, \ldots, \eta_n]^T\) with \(\xi_i, \eta_i > 0\) for all \(i = 1, \ldots, n\), the following hold: (1) \(\|x\|_{\xi,p} \leq \max_i \xi_i^{1/p} |x_{iq}|\); (2) \(\|x\|_{\eta,q} \leq \max_i \eta_i^{1/q} |x_{iq}|\); (3) \(\|x\|_{\xi,\infty} \leq \max_i \xi_i |x_{iq}|\).

This result can be directly derived from Bourbaki (1978). Combining 20 and Proposition 2, we can derive all transaction coefficients between all quadratic norms, \(\| \cdot \|_Q\) with positive definite matrix \(Q\), and all \(\| \cdot \|_{\xi,p}\) for \(\infty \geq p \geq 1\). The same transaction coefficients hold for the equivalence between the matrix norms induced by these vector norms.

**Structured vector norm.** We define a structured vector norm, following the approach presented in Russo et al. (2013). Specifically, assume that \(x \in \{x_1, \ldots, \ x_n\}^T \in \mathbb{R}^n\) can be partitioned into \(K\) vectors \(x_k \in \mathbb{R}^{n_k}\), \(k = 1, \ldots, K\), such that \(x = [x_1^T, \ldots, x_K^T]^T\) with \(\sum_{k=1}^{K} n_k = n\). Let \(|x|_{sk}\) be the norm in \(\mathbb{R}^{n_k}\). Then, the structured norm of \(x\) is denoted by \(\| \cdot \|_G\) and defined as:

\[
|x|_G = ||x_1,s_1, \ldots, x_K|_{sk}|_G
\]

where the norm \(\| \cdot \|_G\) is defined in \(\mathbb{R}^K\). 

\[
\begin{bmatrix}
\| \cdot \|_G
\end{bmatrix}
\]
Given the same partition of $x^k$, $k = 1, \ldots, K$, consider another structured norm $\| \cdot \|_G$ based on using the vector norms $\| \cdot \|_{s^k}$ in $\mathbb{R}^{n_k}$. Let $\tau_k$ be the transaction coefficient from the norm $\| \cdot \|_S$ to $\| \cdot \|_{s^k}$, and $\nu_k$ be the transaction coefficient from the norm $\| \cdot \|_{s^k}$ to $\| \cdot \|_{s^k}$. Then, we have $|x|_G \leq \tau_k |x|_S$ with $U = \text{diag}[\tau_k]_{k=1}^K$.

This result can be derived as a consequence of those presented by Russo et al. (2013).

Russo et al. (2013) showed that contraction analysis can be used to carry out the hierarchical analysis and design of networked systems. Analogously, consider system (18). Partition $x$ into several sub-vectors, $K$ vectors: $x^k \in \mathbb{R}^{n_k}$, $k = 1, \ldots, K$, so that $x = [x^k_1^T, \ldots, x^K_1^T]^T$ with $\sum_k n_k = n$. Each $x^k$ corresponds to the $k$-th subsystem. Then, system (18) can be equivalently written in the following form:

$$x^k = \sum_{k'=1}^K A_{kk'}(t)x^{k'} + B^k, \quad k = 1, \ldots, K,$$

(22)

where $A(r) = \begin{pmatrix} A_{11}(r) & A_{12}(r) & \cdots & A_{1K}(r) \\ A_{21}(r) & A_{22}(r) & \cdots & A_{2K}(r) \\ \vdots & \vdots & \ddots & \vdots \\ A_{K1}(r) & A_{K2}(r) & \cdots & A_{KK}(r) \end{pmatrix}$, $r = 1, 2, \ldots$, and $[B_1^T, \ldots, B_K^T]^T = B$.

The norm of $x$ is defined by (21). Let $A_{ij}(t) = |A_{ij}(t)|_{ij}$, where the norm $\| \cdot \|_{ij}$ is defined by

$$|A_{ij}(r)|_{ij} = \sup_{|x|_{ij} = 1} |A_{ij}(r)x^j_x|,$$

and consider the reduced $K \times K$ matrix

$$\tilde{A}(r) = \begin{pmatrix} \tilde{A}_{11}(r) & \cdots & \tilde{A}_{1K}(r) \\ \vdots & \ddots & \vdots \\ \tilde{A}_{K1}(r) & \cdots & \tilde{A}_{KK}(r) \end{pmatrix}, \quad r = 1, 2.$$

Let $\| \cdot \|_{S_1}$ and $\| \cdot \|_{S_2}$ be two norms in $\mathbb{R}^K$ and $\beta_{12}$ and $\beta_{21}$ be their transaction coefficients such that $\| \cdot \|_{S_1} \leq \beta_{12} \| \cdot \|_{S_2}$ and $\| \cdot \|_{S_2} \leq \beta_{21} \| \cdot \|_{S_1}$. We take the multiple norms in $\mathbb{R}^n$ as $\| \cdot \|_{G,r} = |A(r)|_{S,r}, r = 1, 2$. Let $\mu_{G,r}$ be the matrix measure induced by the vector norm $\| \cdot \|_{G,r}$ in $\mathbb{R}^n$ and $\mu_{S,r}$ be that of $\| \cdot \|_{S,r}$ in $\mathbb{R}^K$. Then, it can be derived that $\mu_{G,r}(A(r)) \leq \mu_{S,r}(A(r))$ (Russo et al., 2013). Proposition 3 implies that $\beta_{12}$ and $\beta_{21}$ can be the transactions coefficients between $\| \cdot \|_{G,1}$ and $\| \cdot \|_{G,2}$ as well.

Therefore, suppose that switched system (18) is in the block-wise form (22). Then, Corollary 1, specifically inequality (19), can be fulfilled assuming that it holds that $(1/2) \left[ \mu_{S,1}(\tilde{A}(1)) + \mu_{S,2}(\tilde{A}(2)) + fr \cdot (\log \beta_{12} + \log \beta_{21}) \right] < -c.$

5 Synchronization in switched networks

Finally, we consider a network example inspired from one first presented in di Bernardo et al. (2014). We assume the network equation is given by

$$\dot{x}^i = f(x^i(t)) - k\sigma(t) \sum_{j=1}^m L_{ij} x^j(t), \quad i = 1, \ldots, m.$$ (23)

Here, $x^i \in \mathbb{R}^n$ stands for the state vector at node $i$, $f(\cdot) : \mathbb{R}^n \to \mathbb{R}^n$ the node dynamics, $k$ is the coupling strength, $L = [L_{ij}]_{i,j=1}^m$ is the Laplacian matrix associated with a graph $G = [V, E]$, where $V = \{1, \ldots, m\}$ is the node set and $E$ the link set, by the way that for each $(i, j)$, $L_{ij}$ takes value $-1$ if there is a link from node $j$ to $i$ and 0 otherwise, and $L_{ii} = -\sum_{j=1}^m L_{ij}$. $\sigma(t)$ takes values 0 or 1, implying that the diffusive coupling among the nodes in the graph $G$ is only active when $\sigma(t) = 1$ while it is not present when $\sigma(t) = 0$. $\Gamma \in \mathbb{R}^{n \times n}$ stands for the inner coupling matrix. We can rewrite (23) in compact form as:

$$\dot{x} = F(x(t)) - k[\sigma(t)\Gamma]x(t)$$

(24)

where $x = [x_1^T, \ldots, x_m^T]^T \in \mathbb{R}^{mn}$, $F(x) = [f^T(x_1), \ldots, f^T(x_m)]^T$ and $\otimes$ is the Kronecker product. Assume that $\tilde{L}$ is diagonalizable, i.e., there exists a nonsingular $Q \in \mathbb{R}^{mn}$ such that $\tilde{L} = Q^{-1}JQ$ with a diagonal matrix $J = \text{diag}[\lambda_j]_{j=1}^m$, where $\lambda_j, j = 1, \ldots, m$, are the eigenvalues of $J$, which are assumed to be real. Without loss of generality, we can assume that $0 = \lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_m$. Note that $\lambda_1 = 0$ is associated with the synchronization eigenvector $[1, \ldots, 1]^T$.

Following similar arguments to those by Carroll & Pecora (1991); Russo & di Bernardo (2011); di Bernardo et al. (2014); Yi et al. (2013), synchronization of network (24) can be achieved if the following linear systems (obtained via linearisation and block diagonalization of (24)):

$$\dot{\phi} = [Df(w(t)) - k\lambda_i\sigma(t)]\phi, \quad i = 2, \ldots, m,$$

(25)

are contracting, where $w(t)$ is a solution of the uncoupled
system
\[ \dot{w} = f(w), \quad (26) \]
and \( Df(\cdot) \) is the Jacobian of \( f(\cdot) \). Assume

\( \mathcal{H}_5 \): System (26) has an asymptotically stable attractor \( A \) (see Yi et al., 2013, Assumption 2).

**Definition 4** System (23) is said to synchronize if there exist \( \delta > 0 \) such that for any \( x^i(t_0) \in B(A, \delta) \), \( \lim_{t \to \infty} |x^i(t) - x^j(t)| = 0 \) for all \( i, j = 1, \cdots, m \). Here, \( B(A, \delta) = \{ y : \inf_{z \in A} |y - z| \leq \delta \} \) denotes \( \delta \)-neighbourhood of set \( A \).

According to Corollary 1, in particular, equation (16), we have the following result:

**Proposition 4** Consider two vector norms \( | \cdot |_0 \) and \( | \cdot |_1 \), which induce two matrix measures \( \mu_0(\cdot) \) and \( \mu_1(\cdot) \) respectively. Suppose that \( \mathcal{H}_4 \) holds and \( \mu_1(-\Gamma) \leq 0 \). If there exist \( T_0 > 0 \) and \( c > 0 \) such that

\[
\begin{align*}
1 \left[ \frac{\mu_0(Df(w))T_0(nT, (n+1)T)}{T} + \mu_1(Df(w)) - k\lambda_2 \Gamma T_0(nT, (n+1)T) \\
+ \mu_1(Df(w)) - k\lambda_2 \Gamma T_0(nT, (n+1)T) \\
+N_{x_0}(nT, (n+1)T) \log \beta_{10} \\
+ N_{x_0}(nT, (n+1)T) \log \beta_{10} < -c
\end{align*}
\]

holds for all \( T > T_0 \) and \( w \in \mathcal{A} \), where \( \mathcal{T}_w(s, t) \) stands for the duration of \( \sigma(t) = u \) in the time interval \( (s, t) \) and \( N_{x_0}(s, t) \) is the number of switches from \( \sigma(t) = u \) to \( \sigma(t) = v \), for all \( u \neq v, u, v = 0, 1 \), then system (24) synchronises.

**Proof** Note that for each \( i = 2, \cdots, m \),

\[
\begin{align*}
\mu_1(Df(w) - k\lambda_2 \Gamma) \\
\leq \mu_1(Df(w) - k\lambda_2 \Gamma) + k(\lambda_i - \lambda_2) \mu_1(-\Gamma) \\
\leq \mu_1(Df(w) - k\lambda_2 \Gamma).
\end{align*}
\]

Due to \( \mu_1(-\Gamma) \leq 0 \), then (27) holds for all \( i = 2, \cdots, m \). It can then be proved in a straightforward manner that the variational equations (25) are asymptotically stable for all \( i \geq 2 \) by verifying condition (16) and following the same steps of the proof of Theorem 5.1 in di Bernardo et al. (2014). Thus, following the arguments in the proof of Theorem 17 in Yi et al. (2013), there is an invariant open convex set \( U \in \mathbb{R}^{m,n,m} \) such that \( U \supset \mathcal{S} \), where \( \mathcal{S} = \{ x = [x^1, \cdots, x^m] : x^i = x^j \in A, \forall i, j \} \), is invariant for the coupled system (24). Furthermore, \( \mathcal{S} \) is an asymptotically stable set for system (24). This proves synchronization.

To illustrate this result, we take

\[
f(w) = \begin{cases} 
\{ p(G[-w_1 + w_2] - g(w_1)) \\ G[w_1 - w_2] + w_3 \\ -qw_2, \end{cases}
\]

where \( g(w_1) = m_0w_1 + 1/2(m_1 - m_0)(|w_1 + 1| - |w_1 - 1|) \) as the Chua circuit with \( m_0 = -0.5, m_1 = -0.8, G = 0.7, p = 9 \) and \( q = 7 \), which was reported to exhibit a double-scroll chaotic attractor for the node dynamics (26) Matsumoto et al. (1985). Moreover, we take \( \Gamma \) as the identity matrix, and assume the underlying graph of 10 nodes has the structure shown in Fig. 3, associated with a Laplacian \( L \) with \( \lambda_2(L) = 2.7142 \). To study convergence, we choose weighted 1-norms: \( |y|_0 = |y_1| + r_2|y_2| + r_3|y_3| \), where \( r_2 = 3.4042 \) and \( r_3 = 1.0369 \), and \( |y|_1 = \sqrt{|y_1|^2 + |y_2|^2 + |y_3|^2} \), which implies (i) \( \beta_{01} = 4.3163 \) and \( \beta_{10} = 1 \); (ii) \( \mu_0(Df(w)) \leq 3.2829 \) for all \( t \). We take \( k = 1 \), so that \( \mu_1(Df(w) - k\lambda_2(L)\Gamma) \leq -7.4714 \), for all \( t \). The switching signal \( \sigma(t) \) is taken as follows:

\[
\sigma(t) = \begin{cases} 
0 & t \in [kT, kT + 1/4T) \\
1 & t \in (kT + 1/4T, (k+1)T) 
\end{cases}
\]

for some \( T > 0 \). Condition (27) in Proposition 4 implies that if \( T > 13.08 \), then system (24) synchronises. To illustrate this result, we take \( T = 14 \). Fig. 4 shows that, as expected, all nodes synchronise.

**6 Conclusions**

We have presented an extension of contraction analysis to switched Carathéodory systems. The key step was the definition of switched matrix measures induced by multiple norms. Using these measures, it was possible to derive different sets of sufficient conditions for asymptotic incremental stability of the systems of interest. Most notably, it was possible to prove contraction and hence incremental stability by using different norms, each associated to a different
mode of the switched system under investigation. This complements and extends in a highly nontrivial manner to the case of multiple norms, previous results presented by some of the authors (see Russo et al., 2013; di Bernardo et al., 2014), where contraction was studied by using a common metric. The theoretical results were illustrated on a set of representative examples and applications showing the effectiveness of the proposed method.
